

Data Analysis with Polars and Python

Nice to meet you!

Boris Paskhaver

- Software Engineer/Consultant
- Teacher
- Author of Pandas in Action

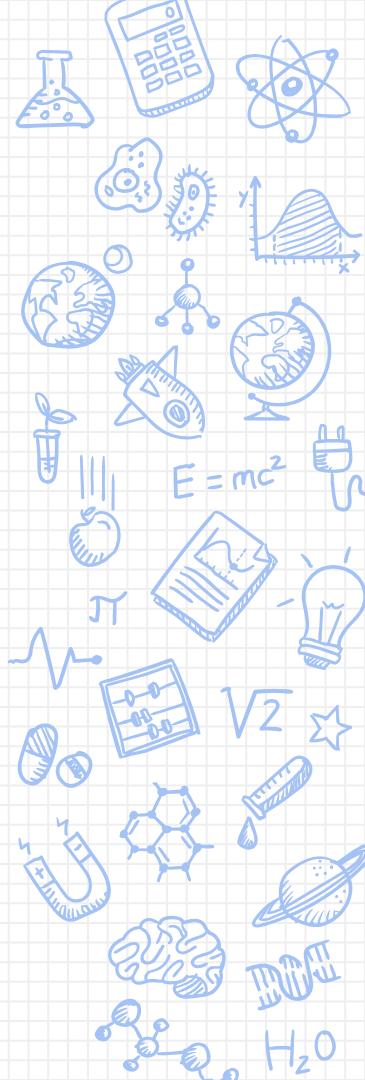

Data Analysis

The process of deriving an insight from a dataset to drive a decision

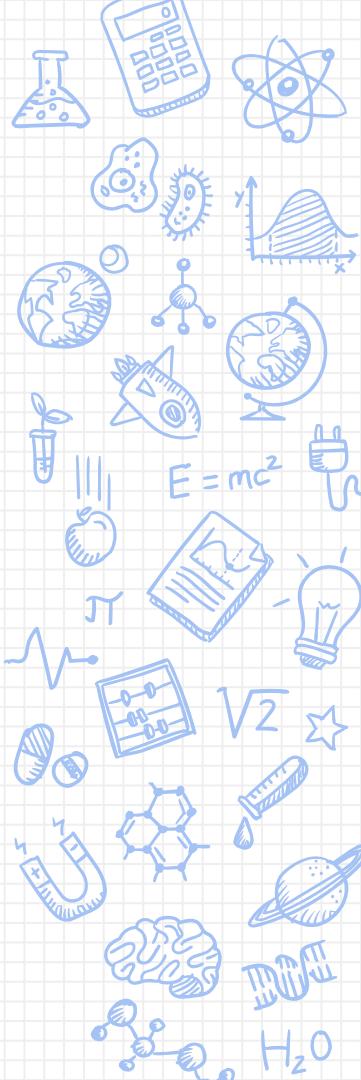

What is Polars?

- ✗ A fast tool for importing, sorting, filtering, grouping, joining data, and more
- ✗ A data analysis library written in Rust with bindings for Python
- ✗ A side project by developer Ritchie Vink
- ✗ 35,000+ stars on GitHub

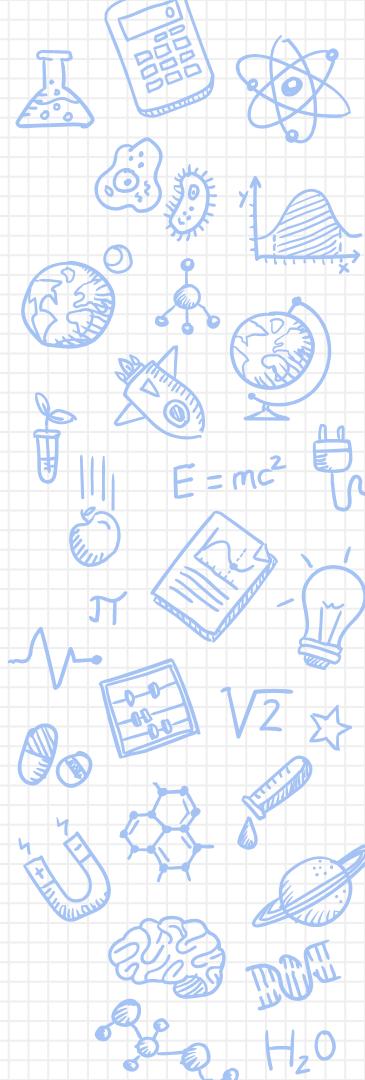

Why is it called Polars?

- ✗ Some consider Polars the successor to the popular Pandas library
- ✗ Pandas is short for “panel data structures” (3-dimensional datasets)
- ✗ Polar bears are more powerful than panda bears
- ✗ Rust files have a “.rs” extension. Polars conveniently ends in “rs”.

What sets Polars apart?

- ✗ Built for speed and efficiency from the ground up, taking advantages of Rust's features
- ✗ Parallelizes computations across multiple threads and CPU cores
- ✗ Uses the columnar Apache Arrow data storage format to optimize column-based operations
- ✗ Supports lazy evaluation with query optimizations

The Plan

- ✖ Download the course materials from GitHub. They include both the datasets and complete / incomplete Jupyter Notebooks.
 - ✖ Use the **uv** command-line tool to install Python, Polars, and the JupyterLab coding environment
 - ✖ **[OPTIONAL]** Complete the Python bootcamp to learn the fundamentals of the language
 - ✖ Dive into the Polars library.
